

# general\_feedback\_assignment\_1

Lau Møller Andersen

- remember that the summary of an ANOVA only gives you comparisons to the base level. Better to report the ANOVA first and then do the comparisons afterwards
- add error bars on plots where relevant
- poisson data: we cannot be modelling slopes for categorical factors (PAS); what are we modelling instead
- remember to answer all questions; that is: provide summaries in text when asked to
- when you refer to values, such as p and b, make sure to show the code that provided them.
- When talking about significance, make sure you say what is significant: what is the contrast being tested. You cannot just say that, say, PAS2 is significant. What is it compared against?
- Be careful, many of you are mixing up likelihood and AIC; - and also make sure to provide the commands from where your AIC and log-likelihood values come from; don't just write them in text
- Be careful; p-values don't tell if something is better than anything else; it talks about the probability of observing the given test statistic: t, F, chi, given that the null hypothesis is true. If that probability is lower than our alpha value, we reject the null hypothesis
- in anova, you can include all models, e.g. `anova(model.0, model.1, model.2)` to compare all in one command
- in your text summaries, make sure to relate back to the experiment. Don't just describe the distributions. Also indicate what can be inferred from it in terms of an experiment
- Plots are beautiful; some few tips for improvement: use bar plots for counts; base the plots on the full model (with interactions) even if that is not your chosen model
- Remember; don't show enormous summaries; (you're much better at not doing it, but there are still a few around)
